---

## Pseudocode

---

### Brute Force:

```
BruteForce(arr)
    count = 0
    for i in 0 to arr.length
        for j in i to arr.length
            if arr[i] > arr[j]:
                count++
    return count
```

### Naive Divide and Conquer:

```
NaiveDivideAndConquer(arr)
    count = 0
    if len(arr) < 2:
        return count
    middle = length(list_in)/2
    left = arr[:middle] // slice off half of the array
    right = arr[middle:]
    // count inversions between left and right halves
    for i in range(0, len(left)):
        for j in range(0, len(right)):
            if left[i] > right[j]:
                count++
    // and count internal inversions recursively
    count += NaiveDivideAndConquer(left)
    count += NaiveDivideAndConquer(right)
    return count
```

### Merge and Count:

```
MergeAndCount(arr, 0)
    results = []
    // base case
    if len(x) < 2:
        return x, count
    middle = len(x)/2
    // recursive calls
    left, count = MergeAndCount(x[:middle], count)
    right, count = MergeAndCount(x[middle:], count)
    i, j = 0, 0
    while i < length(left) and j < length(right):
        if left[i] > right[j]:
            results.append(right[j])
            count += length(left) - i
            j++
        else:
            results.append(left[i])
            i++
    results += left[i:]
    results += right[j:]
    return results, count
```

---

## Correctness Proof

---

## Asymptotic Analysis of Run Time

---

**Brute Force:** It has two for loops of size  $n$  duh

**Naive Divide and Conquer:**  $T(n)$  = this class is difficult

**Merge and Count:**  $T(n)$  = wow such recursion

## Testing

---

The first test for correctness was performed using the provided file “verify.txt”. It was assumed that the last value of each row was the expected number of inversions, so all 3 algorithms were run on each row of values (excluding the last), and this was compared to the expected value. This can be performed via: “test\_correctness1(“verify.txt”)”.

The second test for correctness used the second provided file “test\_in.txt”. Since no expected values were given, the results were just printed out. All 3 algorithms gave the same value, so this is a good indication. The results have been included below, with just a single value given (number of inversions) for each row in the test file. This test can be run by calling the function “test\_correctness2(“test\_in.txt”)”.

Results: 252180, 250488, 243785, 247021, 250925, 256485, 249876, 253356, 255204, 247071

## Extrapolation and Interpretation

---

Slope of lines in log-log plot:

The equation for the best fit line on the log-log plot (calculated using `numpy.polyfit()`) has the following form:

$$f(n) = e^y - intercept * n^{slope}$$

Brute Force

- slope: 2.014
- y-intercept: -16.3

Naive Divide Conquer

- slope: 1.89
- y-intercept: -15.3

---

Merge Count

- slope: 1.10
- y-intercept: -12.3

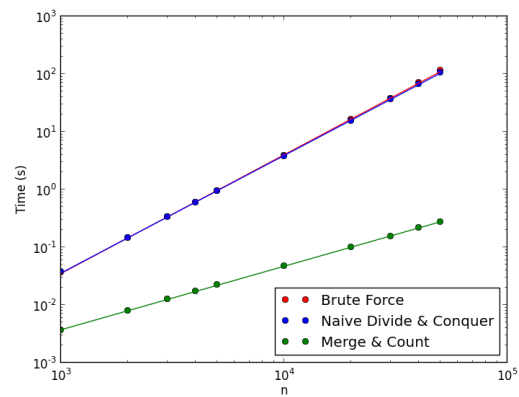

Largest input item solvable in an hour:

Discrepancy between actual and asymptotic:

## Empirical Analysis of Run Time

---

Log-log Plot:

Input size vs. Time:
